INTRODUCTORY GROWER’S GUIDE

Cultivation of shiitake mushrooms is a fairly simple process. This guide will help you plan for an effective cultivation experience and give you some insight before you have the logs out and ready to grow mushrooms. Keep in mind that this process is slightly different for each grower as will benefit from personal adjustments as you become a more accomplished grower. Here is how we do it and some advice we learned along the way.

ABOUT SHIITAKE (LENTINULA EDODES)

Shiitake Form: fleshy convex cap, slightly tough stalk
Color: light to dark brown cap, creamy white gills, light brown stem
Best grown on: hardwoods like oak, maple, ironwood
Spawn form available: plug, grain, sawdust
Average size at harvest: 3-6 inch diameter cap, 2-4 inch stalk
Odor/flavor: robust, earthy
Does it grow wild in the United States: No

BACKGROUND:
The origins of Shiitake cultivation have been traced back thousands of years to Japan. People often found these mushrooms growing on downed ‘shii’ trees (this is where the mushroom got its name). People would take the mushroom-clad logs, place them next to logs without mushrooms and simply wait for the wind to disperse the spores. Thankfully, since then, a lot of research in Japan and China has gone into Shiitake-growing techniques, and we don’t have to wait for the wind anymore. In fact, Shiitake is the second most produced mushroom in the world, following the common button mushroom.
Choosing a Laying Yard

Before you begin, think about where you are going to keep all the logs once they are inoculated with mushroom spawn. This will become the ‘laying yard’: the place where the logs are incubated and routine “maintenance” is performed. The logs usually remain in the laying yard for the rest of their productive lifetime, which includes both fruiting and harvest.

**IMPORTANT FACTOR TO CONSIDER**

### Year-round shade (75-100%) and high humidity

Almost nothing is more important than laying (incubating) the logs under year-round shade in order to keep the logs from drying out due to sun and wind. A laying yard beneath the canopy of a coniferous forest is best. A deciduous canopy will suffice but it will be necessary to protect the logs with 80% shade cloth or pine boughs during the winter.

### Access and Relative Location

Ideally the laying yard should be assessable by a vehicle or tractor and close to your home/farm. You should also consider its proximity to electric (necessary to inoculate the logs) and water (necessary to irrigate and soak the logs). You do not want to place a laying yard in any location that necessitates carrying the log over any great distance.

### Proximity to Water and Water Source

A water source is necessary for forced fruiting (shocking) as well as for maintaining a threshold moisture level in the logs. Take into consideration how close and convenient each possible water source is. Particularly think about moving materials through the laying yard and common use patterns. If there is a dry spell and the logs must be wetted to maintain moisture levels, logs may be submerged under water or dampened under a sprinkler. It is critical that the moisture content of the logs does not fall below a threshold level necessary for the survival of the mycelium. Logs typically begin at about 40–45% moisture content and should not drop below 25%. Ideally the water should come from a well or stream (chlorinated public water will harm the mycelium), cool, and clean.

### Other important aspects

Other important aspects of the laying yard include slope, microclimate, aspect, and accessibility. The slope and microclimate of the laying yard will affect how you lay the logs. A north or northeast aspect is ideal. For example, if it is a site with lots of exposure to wind, one may choose to lay logs closer together to maintain log moisture.

**Materials Checklist: Outdoor Shiitake Cultivation**

- Access to water for force fruiting.
- A cultivation area with modest shade and protection from wind.
- Hardwood logs cut from healthy saplings or pole-size trees, or from tops of larger trees.
- Spawn and plunging tool: (Spawn and the following supplies can be purchased from professional supplier.)
- Cheese wax: For sealing spawn.
- Daubers: For applying cheese wax.
- Very high speed drill, available from professional suppliers. If you only purchase one piece of equipment, it should be the highest speed drill you can find.
- Appropriate drill bits.

---

**Who is doing what and when?**

- Tree selection and harvesting logs (Winter and Spring of Year 1)
- Inoculation and stacking (Spring of Year 1)
- Laying yard maintenance (Continuous)
- Mushroom harvesting (Summer and Fall Year 2)
- Marketing and Sales (Summer and Fall Year 2)
- Delivery/Distribution (Summer and Fall Year 2)

Worksheet for Mushrooms Yard Assessment

Assessments help us choose species and elements that are appropriate to the environmental conditions and also help determine where to place them on the landscape to maximize production and minimize the expenditure of time, energy, and resources. For example, if I am looking to design a mushroom laying yard, good criteria include:

- Reliable access to water for soaking
- 60 – 100% shade (year-round) and high humidity
- Good ventilation/air flow
- Windbreaks (to keep logs from drying out)
- Good access for people and equipment
- Use of marginal landscapes less ideal for other uses (sloped)

Describe the overall site(s). Consider factors like climate, landform, existing vegetation/wildlife, infrastructure, patterns and current uses.

What Tree Species to Use

OAK

Oak is often considered the species of choice for shiitake production in North America. Research at the Center for Agroforestry has shown that red and white oak performed about the same as substrates for shiitake. Because oak is a valuable timber species, forest owners who include timber production as part of their woodland management goals may be reluctant to cut large amounts of young oak for shiitake cultivation. However, tops left after logging are often of an appropriate size to be used as bolts although timing might be less than optimal for mushroom production.

OTHER EXCELLENT SPECIES

A number of other species have been shown to be as productive at oak. These include: American beech (*Fagus grandifolia*), Sugar maple (*Acer saccharum*), American hornbeam (*Carpinus caroliniana*) and Hophornbeam (*Ostrya virginiana*).

OTHER POSSIBLE OPTIONS

We have no experience with Chestnut, Ash, Alder, Elm, and Tupelo. Although we don’t know how well these species will perform, we encourage you to try them out if the trees are available.

WHAT NOT TO USE

Don’t use the wood from any evergreen tree (pine, spruce, hemlock, etc.) We also don’t recommend using birch or aspen.

BUYING BOLTS

You may also consider buying pre-cut lengths (cost $1.00 - $2.00 / bolt). Buyers should try to purchase logs in good condition with the bark intact, and few places of rot or scarring. Be sure to ask when logs were cut, what the storage conditions prior to delivery or pick-up were. Remember that if the logs were stored in the sun, the moisture content is likely to be too low.

Ideas to Help you Develop a Market

- Talk with people in your area. Get your name and business out there so people know what you sell and how they can reach you.
- Offer free samples, recipes, or pamphlets to help customers realize how tasty and fun mushrooms can be.
- Talk with local chefs to see if they might be interested in your product. It’s nice if you have some information to leave them that has your contact info clearly visible.
- Ask if they would like you to bring in sample product. Perhaps they would like some to trial before they buy.
- If certain restaurants are willing to buy particularly large quantities, consider offering a bulk discount.
- Grocery stores will most likely pay lower prices than selling at other venues, but can handle a lot of product on a regular basis.
- Stores that put emphasis on buying locally or eating healthy foods are good choices for your product. At the right venue, your buyers will be pleased to have a great product like yours that makes the store look good to consumers.
- Make sure that the mushrooms you are selling are always top quality.
- Try to be consistent with delivery times and quantities. If you have promised a certain amount of product, make sure you have planned that into your rotation schedule.

**DEVELOP A MARKETING PLAN**

- Identify market area
- Identify target markets
- Identify competition (may be your best partner)
- Decide on marketing tools (logo, newsletter, website, signage, discounts, etc.)
- Determine success (# of customers, new and repeat sales, income, etc)

When to Cut the Tree Down

Mushroom growers who are forest owners (or have a working relationship with forest owners) should establish a management plan for their woodlot and have training in the safe use of a chainsaw.

Only living trees should be cut down. It is important to have fresh logs for inoculation because they have a high moisture content, little or no competing wild fungi, which are two important factors for successful mushroom cultivation. If you are cutting your own trees, it is best done late winter or early spring; at least a couple of weeks before bud-swell. This is also the time when the bark is tightest around the trunk and will prevent early bark loss later on. An intact bark is a very important component of the log in order for it to retain moisture and block pathogens from entering the log.

Optimal Size of Logs/Bolts

Logs are typically 4-6 inches in diameter. Larger logs can be used but they are obviously more difficult to manage. This diameter range was chosen because it optimizes the amount of sapwood per volume of log. The sapwood is the primary part of the log that the fungi will colonize. Length is not as pertinent as diameter for health of the fungi, but a 3 to 4 foot long is manageable for transport and individuals to carry.
WHEN TO INOCULATE...

We recommend that the logs be stored between two to four weeks before being inoculated. Regardless of how long you wait to inoculate, do not store bolts in the sun. If a log is cut and left to sit for an extended period of time before inoculation other species of fungi can invade the log or log can dry out.

WHAT TYPE OF SPAWN TO USE

Bolts can be inoculated with sawdust spawn or of plug spawn. There are advantages and disadvantages to each. Plug spawn is very simple to use—the only tool needed is a hammer or mallet. The drawbacks are that plug spawn is slightly more expensive per log than sawdust spawn, and the mycelium may take a while to migrate out from the plug spawn. Sawdust spawn is slightly cheaper than plug spawn, but it requires a special tool, either purchased or home made, to insert the sawdust in the hole. In addition to its lower cost, the mycelium contained in sawdust spawn moves out into the log more quickly, giving somewhat faster production. Other than that, the methods are the same between inoculating logs with plug spawn and with sawdust spawn.

THE DOWEL INOCULATION METHOD

We recommend reviewing the video at http://mushrooms.cals.cornell.edu/cultivation.htm for step by step directions regarding drilling and inoculation.

- Drill holes, 5/16” diameter, 1’ deep, every 4 inches along the log. Rotate log and repeat. To create a diamond pattern, shift the 2” down along the guide for every other row. Typically 1 row of holes is drilled for every inch of log diameter.
- Place a plug (dowel) spawn in each drilled hole and hammer it into the log. Each plug should lie just below flush with the log surface.

WHEN AND HOW TO HARVEST

It is not the size of the mushroom that determines when it is picked, but its growth progress. Gills should be visible and the outer edge of the mushroom should be slightly curled under, but not tightly so. If the edge has flattened out, the mushroom is slightly over ripe, but still edible. Shiitake are usually ready 7 - 10 days after shocking; colder temperatures will slow growth and ideal conditions will make it more rapid. Using a knife is quick, easy, and ensures a clean cut on the stem. It also does not rip or damage any bark.

HOW MUCH TO EXPECT

Mushroom production for a typical log will peak the second and third years. At this time it is reasonable to expect 0.25-0.5 lb per log or higher per flush, with the goal of doing two shockings per season.

STORING FRESH MUSHROOMS

Never store fresh mushrooms in a plastic bag. Use paper bags and keep them refrigerated. Mushrooms will keep under refrigeration for up to one week.
Fruiting Shiitakes

In a natural production model, growers do not do anything to the mushroom logs to make them fruit. Logs are left to fruit naturally, flushing either when there is heavy rainfall or when a temperature change encourages fruiting. In a forced production model, growers control when logs fruit. Logs may sometimes also fruit naturally, (in fact, heavy rain can knock production schedule way out of whack) but the majority of harvests are induced according to a preplanned log rotation schedule. Because yields can be predicted and kept relatively constant in this model, it has greater retail potential.

SHOCKING

Shocking, or forcing, is the process used to force mycelium into fruiting body (mushroom) production. Soaking logs in cold water for an extended period of time will induce fruiting. Place the logs in the coldest water you have available — a 100 gallon cattle trough or big tub works best. Because temperature adjustment is not practical, we recommend a fast moving stream or tank kept out of sun. Leave the logs submerged in the water for 12 to 24 hours. Remove the logs from the water and stack them in an A frame conducive to the upcoming harvest. In 3 – 5 days, the log will begin pinning, or sending up the beginnings of mushrooms. These will grow and develop into full-sized shiitake mushrooms.

HOW OFTEN TO SHOCK

After fruiting, logs need to be rested for 6 - 8 weeks before being forced again. The more often the logs are shocked, the shorter their lifetime is likely to be. We recommend only shocking once during first production year, then twice during year second and third.

Logs should be stacked in the laying yard so they are easily identified in order to establish a schedule for shocking and harvesting. This plan should take into account the number of times each log will be forced a season, when logs will be forced, how logs will move through the laying yard, when mushrooms are needed, when the plan predicts mushrooms will be available, and when logs will be retired at the end of their lifetime.

THE SAWDUST INOCULATION METHOD

The first step in inoculation is drilling holes into the bolt. For sawdust-based inoculation, use a 7/16" drill bit size and drill to a depth of 1.25". We recommend a drill bit with a built in drill stop; it is better than the adjustable drill stop you purchase in a common hardware store. More holes are not detrimental and in fact are likely to speed up colonization of the log.

After the holes are drilled, it is time to place the spawn in the holes, bringing the shiitake mycelium in contact with its new food source (substrate), the log. Stab the inoculation tool into the spawn and pound it once or twice to inject the spawn taking care that the tool is full place the tool over the hole and depress the plunger at the top to compact the spawn into the hole; the hole should be full so that the spawn is level with or just below the surface of the log. Repeat this process for all holes.

© Nicholas Laskovski—Dana Forest Farm

DRILL OR ANGLE GRINDER?

Outfitting an angle grinder with a drill bit is another method of drilling holes into the log. (This required an adaptor for the angle grinder.) While equipping an angle grinder with a drill bit is expensive, it is possible to move very quickly with this tool, reducing the time spent per log. They are especially useful for larger operations.
Waxing the Logs

Waxing the holes helps seal in moisture so that the spawn does not dry out. By sealing off the holes, the chance of contamination by competing fungi species is reduced. During this step each hole is completely sealed using food grade wax. Electric skillets work particularly well to melt the wax however, you have to put a pot on the electric skillet to hold the wax. A skillet alone is too shallow and dangerous. They are sturdy, portable, and the temperature control is easy. You can also heat the wax in a pot over a portable propane or white gas stove. Wax should be heated to 350-400 degrees (wisps of smoke).

You can apply the wax in a number of different ways. Foam paint brushes ($0.50 - $0.80 / brush) are very effective and many people already own a foam paint brush. One inch brushes work best. These can be reused many times (until the brush comes off of the wooden handle). Cotton daubers ($30.00 / 144 pc = $0.21 / 1pc) are cheaper than foam paint brushes, these small cotton balls on the end of a wire handle are available from select mushroom product suppliers. They can be reused and are very effective.

To apply the wax, use the chosen applicator to transfer the hot wax onto each hole in the log. Care should be taken to seal the hole. One dip of the applicator should complete a few holes.

WAXING THE ENDS

Some growers choose to wax the ends of each mushroom log either by dipping the log directly into the pot of melted wax or by painting each end with a paint brush soaked in wax. Other growers choose to skip this step. An experiment at Cornell's Arnot Forest found no difference in mushroom production between end-waxed and non waxed log ends. The importance of this step may vary based on climate, which largely governs how crucial it is to strictly manage moisture levels. Waxing the ends will keep moisture in and prevents competitive fungi from gaining a foothold. However wax also is one of the main production costs and the waxing process adds considerable time to the inoculation process. A cost-benefit analysis of additional wax cost and shiitake yield has not yet been conducted.

Stacking Logs

CRIB STACK (RICK STACK)
Crib stacks are simple and quick to make. First four to five logs are laid down on a flat surface, then four to five logs are placed on top of them in the opposite direction; the pattern is continued for about five levels. Crib stacks are a very space efficient way to keep logs as they make use of vertical space, compactly storing large numbers of logs. This stacking method is excellent for the spawn run period.

HIGH A-FRAME
A high A-frame consists of logs leaning upright on one or two sides against a supporting beam, such as a cut sapling lashed horizontally onto two trees or a taut wire. This stacking method works well for the fruiting and harvest stages. Logs are well aerated, mushrooms are easily visible, and picking is easy as there is maximum access to each log. Because the log is vertical, slug damage to mushrooms may be less than when logs are fruiting closer to the ground. Because logs stacked in A-frames take up a lot of space in a laying yard, they are usually not left on the A-frame for any other part of the process; this is especially true for a forced production model.

JAPANESE HILLSIDE METHOD
This stacking method is more complex to set up, and only recommended for steep hillsides. This technique creates a very stable, aerated stack in which mushrooms are highly visible and easy to pick. The majority of logs are raised off the ground, potentially reducing slug damage. For more information on this stacking method see “Our Cultivation Guides” featured on the Northern Mushroom Growers Website at http://mushrooms.cals.cornell.edu/
